Project #2
Due: 9/23/24

AI Usage Disclaimer:

N-Grams Algorithm

Assignment Requirements:

Input

- Two training data input files
  - CNN Stories
  - Shakespeare Plays
- Each line in the files are paragraphs, and paragraphs may contain multiple sentences

Processing

- Text will be converted to lowercase during processing
- Extract n-grams in both methods
  - Sentence level
    - Paragraph will be sentence tokenized (NLTK sent_tokenize), then all sentences will be word tokenized (NLTK word_tokenize)
      - Resulting data will be augmented with <s> and </s>
  - Paragraph level
    - Paragraph will be word tokenized (NLTK word_tokenize)
      - Resulting data will be augmented with <s> and </s>
  - n-gram extraction should never cross over line boundaries
- The data structure used to hold tokens in each sentence should start with <s> and end with </s>, according to the n-grams being processed
  - Higher order n-grams require more start symbol augments
- Unigrams, bigrams, trigrams, quadgrams will each be kept in separate data structures
  - Dictionaries, indexed by "context tuples" work well for this
- A parallel data structure should hold the counts of the tokens that immediately follow each n-gram context
  - These counts should be stored as probabilities by dividing by total count of tokens that appear after the n-gram context
- Process both files first using sentence level, then followed by paragraph level

Output

- Set NumPy seed to 0
- Print the count of extracted unigrams, bigrams, trigrams, and quadgrams (for each file)
- For each file, choose a random starting word from the unigram tokens (not)
  - This random word will be used as the seed for generated n-gram texts
- For each gram:
  - Using the seed word (prefixed with <s> as required) generate either 150 tokens or until is generated
    - Do NOT continue after
  - Each next token will be probabilistically selected from those that follow the context (if any) for hat n-gram
  - When working with higher order n-grams, use backoff when the context does not produce a token. Use the next lower n-gram

Python Code

In [149…

```
# Imports libraries and reads corpus documents. Save the documents as raw tokens

import numpy as np
